1 References come first here

- A big shout out to the Youtube channel **MPrashant Academy** for his amazing Linux Shell Scripting video tutorials for beginners which helped me immensely getting started. I add a lot of his slides in this document because they illustrate exactly what one needs.

<https://www.youtube.com/@MPrashantAcademy>

<https://www.instagram.com/mprashant.codes/>

- A very good resource to learn initial concepts in text form: <https://linuxjourney.com/>
- If you need a simple online terminal to practice simple commands I strongly recommend: <https://bellard.org/jslinux/>

2 Linux? Shell? Scripting?

Linux, Shell, Scripting, Bash.... All these terms can be confusing to differentiate so let's break them down:

- **Linux** is an open-source operating system (OS) based on Unix (think of Unix as the ancestor of many OS and the reason CLI exist), it handles hardware resources, runs apps and processes, provides a CLI, handles filesystems, permissions and acts as the layer in between users and programs and the hardware.
- **Shell** is a CLI, a Command Line Interface, the scary dark window, an environment to run your commands, scripts and programs. There are many different shell types, **sh**, **bash**, **zsh**, **fish**, etc.
- **Bash** is a type of Shell, the most popular actually, it extends the features of **sh**.
- **Shell scripting** means writing a sequence of shell commands in a file (called a script) so they can be executed automatically.

2.1 How to check your shell type

```
echo $0
```

2.2 Check the available shell types in your machine

```
cat /etc/shells
```

```
[root@localhost ~]# cat /etc/shells
/bin/sh
/bin/bash
/usr/bin/sh
/usr/bin/bash
/usr/bin/tmux
/bin/tmux
/bin/csh
/bin/tcsh
/usr/bin/csh
/usr/bin/tcsh
/usr/bin/zsh
/bin/zsh
```

2.3 Change shell type

Simply run the name of the shell you want to switch to the shell type you want, if you are in **sh** for exmple just type **bash** in the terminal and run.

```
[root@localhost ~]# echo $0
sh
[root@localhost ~]# bash
[root@localhost ~]# echo $0
bash
```

3 What is vi?

You write your scripts in text editors, a very common one is **vi** (think of 6 in romans), you can also find **vim**, **nano**, **gedit**, etc. To open vi simply run: **vi {name of the file}**, for example **vi test.sh**

Inside **vi** keep in mind:

- **i** to start editing
- **Esc** to stop editing
- **:q** to quit **vi** without saving latest changes
- **:wq** to save latest changes and quit **vi**

Inside your script:

- Use a **shebang line**, this is the first line to add in a script **#!/bin/bash**, is the way **vi** has to tell the OS to use the bash or another shell type to execute the script. It is not a mandatoy line but it's strongly recommended so use it!

```
#!/bin/bash
echo "Hey Buddy!"
```

- Use comments as with any other programming languages.

```
MPRASHANT

COMMENTS

Using #
#This is a comment

Multi-line comment
<<comment
...
your comment here
...
comment

#!/bin/bash
#This is single line comment
echo "Hello"

<<comm
This is
a muli
line comment
comm
```

- It is not mandatory to save your scripts with as a `.sh` but it helps since it clearly indicates that it is a shell script and in editors like Vscode it is helpful due to formatting.

4 It's all about having consent! (Permissions)

You need to have the right permissions to work with scripts, either to read, write or execute.

Check this great explanations by GeeksforGeeks:

<https://www.geeksforgeeks.org/bash-script-file-permissions/>

<https://www.geeksforgeeks.org/set-file-permissions-linux/>

After making sure the permissions are good to go you can run the scripts.

5 Variables

```
#!/bin/bash

#Defining variables
readonly name="Prashant"
age=30

echo "My name is $name and age is $age"

name="Paul"
echo "New name is ${name}"

HOSTNAME=$(hostname)
echo "Name of the server is $HOSTNAME"

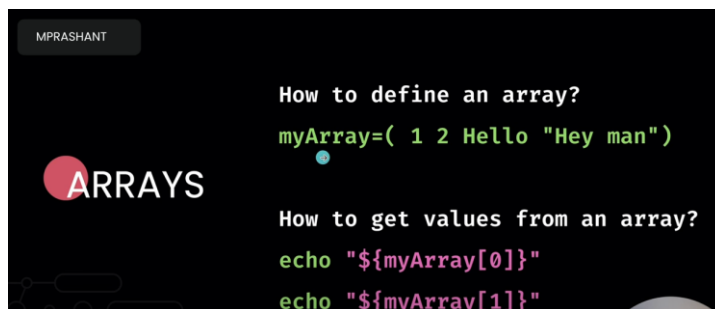

PWD=$(pwd)
echo "We are in path $PWD"

~
```

- Use **readonly** to make variables constant
- Make sure there is no space in between the = sign
- Use `${variableName}` instead of `$variableName` for more readability

6 Arrays

- You can use different data types in a single array
- Each item in the array is separated by a space
- If we have an item like a string that has a space inside it then we surround the item with ""
- Indexes start at 0

7 Strings

Todo

8 Conditionals

Todo

9 Loops

Todo

10 Functions

Todo

11 Misc concepts
